

Questions on Normalizing Flow models

What is the difference between (normalizing) flows and the auto-regressive models we discussed last week?

Why not just model data as a mixture of Gaussian?

What is the main idea of Flows? (Bijective mapping between spaces, change of Variables)

What is optimized flow? What are, therefore, the requirements on the flow?

How can it be trained?

Where is the information on the target distribution contained?

How can flows be parameterized in practice?

What is the difference between auto-regressive flows and inverse auto-regressive flows?

How does RealNVP work?

What is de-quantization? Why do we need de-quantization in practice?
